The Questions-Answers Page

<https://tinyurl.com/bdenpwc5>

Where Are We?

Spark Streaming

Spark Streaming

- ▶ Run a streaming computation as a **series** of very **small**, **deterministic batch jobs**.

Spark Streaming

- ▶ Run a streaming computation as a **series** of very **small**, **deterministic batch jobs**.
 - **Chops up** the live stream into batches of **X** seconds.
 - Treats each batch as **RDDs** and processes them using **RDD operations**.

Spark Streaming

- ▶ Run a streaming computation as a **series** of very **small**, **deterministic batch jobs**.
 - **Chops up** the live stream into batches of **X** seconds.
 - Treats each batch as **RDDs** and processes them using **RDD operations**.
 - Discretized Stream Processing (**DStream**)

DStream (1/2)

- ▶ **DStream**: sequence of **RDDs** representing a stream of data.

DStream (1/2)

- **DStream**: sequence of **RDDs** representing a stream of data.

DStream (2/2)

- ▶ Any **operation** applied on a **DStream** translates to operations on the underlying **RDDs**.

StreamingContext

- ▶ **StreamingContext** is the **main entry** point of all Spark Streaming functionality.

```
val conf = new SparkConf().setAppName(appName).setMaster(master)
val ssc = new StreamingContext(conf, Seconds(1))
```

- ▶ The second parameter, **Seconds(1)**, represents the **time interval** at which streaming data will be divided into **batches**.

Input Operations

▶ Socket connection

- Creates a DStream from text data received over a **TCP socket connection**.

```
ssc.socketTextStream("localhost", 9999)
```

Input Operations

▶ Socket connection

- Creates a DStream from text data received over a **TCP socket connection**.

```
ssc.socketTextStream("localhost", 9999)
```

▶ File stream

- Reads data from **files**.

```
streamingContext.fileStream[KeyClass, ValueClass, InputFormatClass](dataDirectory)  
streamingContext.textFileStream(dataDirectory)
```

Input Operations

▶ Socket connection

- Creates a DStream from text data received over a **TCP socket connection**.

```
ssc.socketTextStream("localhost", 9999)
```

▶ File stream

- Reads data from **files**.

```
streamingContext.fileStream[KeyClass, ValueClass, InputFormatClass](dataDirectory)  
streamingContext.textFileStream(dataDirectory)
```

▶ Connectors with **external sources**, e.g., **Twitter, Kafka, Flume, Kinesis, ...**

Transformations (1/2)

- ▶ Transformations on DStreams are still lazy!
- ▶ DStreams support many of the transformations available on normal Spark RDDs.

Transformations (1/2)

- ▶ Transformations on DStreams are still lazy!
- ▶ DStreams support many of the transformations available on normal Spark RDDs.
- ▶ Computation is kicked off explicitly by a call to the `start()` method.

Transformations (2/2)

- ▶ **map**: a new **DStream** by passing each **element** of the source DStream through a given function.

Transformations (2/2)

- ▶ **map**: a new **DStream** by passing each **element** of the source DStream through a given function.
- ▶ **reduce**: a new DStream of **single-element RDDs** by **aggregating** the elements in each RDD using a given function.

Transformations (2/2)

- ▶ **map**: a new **DStream** by passing each **element** of the source DStream through a given function.
- ▶ **reduce**: a new DStream of **single-element RDDs** by **aggregating** the elements in each RDD using a given function.
- ▶ **reduceByKey**: a new DStream of **(K, V) pairs** where the values for each key are **aggregated** using the given reduce function.

Example - Word Count (1/6)

- ▶ First we create a `StreamingContext`

```
import org.apache.spark._
import org.apache.spark.streaming._

// Create a local StreamingContext with two working threads and batch interval of 1 second.
val conf = new SparkConf().setMaster("local[2]").setAppName("NetworkWordCount")
val ssc = new StreamingContext(conf, Seconds(1))
```

Example - Word Count (2/6)

- ▶ Create a `DStream` that represents streaming data from a `TCP source`.
- ▶ Specified as `hostname` (e.g., `localhost`) and `port` (e.g., `9999`).

```
val lines = ssc.socketTextStream("localhost", 9999)
```

Example - Word Count (3/6)

- ▶ Use `flatMap` on the stream to split the records text to words.
- ▶ It creates a new DStream.

```
val words = lines.flatMap(_.split(" "))
```

Example - Word Count (4/6)

- ▶ Map the `words` DStream to a DStream of `(word, 1)`.
- ▶ Get the `frequency of words` in each `batch of data`.
- ▶ Finally, `print` the result.

```
val pairs = words.map(word => (word, 1))  
val wordCounts = pairs.reduceByKey(_ + _)  
  
wordCounts.print()
```

Example - Word Count (5/6)

- ▶ Start the **computation** and **wait** for it to **terminate**.

```
// Start the computation  
ssc.start()  
  
// Wait for the computation to terminate  
ssc.awaitTermination()
```

Example - Word Count (6/6)

```

val conf = new SparkConf().setMaster("local[2]").setAppName("NetworkWordCount")
val ssc = new StreamingContext(conf, Seconds(1))

val lines = ssc.socketTextStream("localhost", 9999)
val words = lines.flatMap(_.split(" "))
val pairs = words.map(word => (word, 1))
val wordCounts = pairs.reduceByKey(_ + _)
wordCounts.print()

ssc.start()
ssc.awaitTermination()

```

Window Operations (1/2)

- ▶ Spark provides a set of transformations that apply to a over a **sliding window** of data.

Window Operations (1/2)

- ▶ Spark provides a set of transformations that apply to a over a **sliding window** of data.
- ▶ A window is defined by two parameters: **window length** and **slide interval**.

Window Operations (1/2)

- ▶ Spark provides a set of transformations that apply to a over a **sliding window** of data.
- ▶ A window is defined by two parameters: **window length** and **slide interval**.
- ▶ A **tumbling window** effect can be achieved by making **slide interval = window length**

Window Operations (2/2)

- ▶ `reduceByWindow(func, windowLength, slideInterval)`
 - Returns a new **single-element DStream**, created by aggregating elements in the stream over a **sliding interval** using `func`.

Window Operations (2/2)

- ▶ `reduceByWindow(func, windowLength, slideInterval)`
 - Returns a new **single-element DStream**, created by aggregating elements in the stream over a **sliding interval** using `func`.

- ▶ `reduceByKeyAndWindow(func, windowLength, slideInterval)`
 - Called on a DStream of **(K, V) pairs**.
 - Returns a **new DStream of (K, V) pairs** where the values for each key are aggregated using function `func` over **batches in a sliding window**.

Example - Word Count with Window

```
val conf = new SparkConf().setMaster("local[2]").setAppName("NetworkWordCount")
val ssc = new StreamingContext(conf, Seconds(1))

val lines = ssc.socketTextStream("localhost", 9999)
val words = lines.flatMap(_.split(" "))
val pairs = words.map(word => (word, 1))
val windowedWordCounts = pairs.reduceByKeyAndWindow(_ + _, Seconds(30), Seconds(10))
windowedWordCounts.print()

ssc.start()
ssc.awaitTermination()
```

What about States?

- ▶ Accumulate and aggregate the results from the **start of the streaming job**.
- ▶ Need to check the **previous state of the RDD** in order to do something with the **current RDD**.

What about States?

- ▶ Accumulate and aggregate the results from the **start of the streaming job**.
- ▶ Need to check the **previous state of the RDD** in order to do something with the **current RDD**.
- ▶ Spark supports **stateful streams**.

Checkpointing

- ▶ It is **mandatory** that you provide a checkpointing directory for **stateful streams**.

```
val ssc = new StreamingContext(conf, Seconds(1))  
ssc.checkpoint("path/to/persistent/storage")
```

Stateful Stream Operations

▶ `mapWithState`

- It is executed only on set of keys that are available in the **last micro batch**.

```
def mapWithState[StateType, MappedType](spec: StateSpec[K, V, StateType, MappedType]):  
  DStream[MappedType]
```

```
StateSpec.function(updateFunc)
```

```
val updateFunc = (batch: Time, key: String, value: Option[Int], state: State[Int])
```

Stateful Stream Operations

▶ `mapWithState`

- It is executed only on set of keys that are available in the **last micro batch**.

```
def mapWithState[StateType, MappedType](spec: StateSpec[K, V, StateType, MappedType]):  
  DStream[MappedType]
```

```
StateSpec.function(updateFunc)
```

```
val updateFunc = (batch: Time, key: String, value: Option[Int], state: State[Int])
```

- ▶ Define the update function (**partial updates**) in `StateSpec`.

Example - Stateful Word Count (1/4)

```
val ssc = new StreamingContext(conf, Seconds(1))
ssc.checkpoint(".")

val lines = ssc.socketTextStream(IP, Port)
val words = lines.flatMap(_.split(" "))
val pairs = words.map(word => (word, 1))

val stateWordCount = pairs.mapWithState(StateSpec.function(updateFunc))

val updateFunc = (key: String, value: Option[Int], state: State[Int]) => {
  val newCount = value.getOrElse(0)
  val oldCount = state.getOption.getOrElse(0)
  val sum = newCount + oldCount
  state.update(sum)
  (key, sum)
}
```

Example - Stateful Word Count (2/4)

- ▶ The **first micro batch** contains a message **a**.

Example - Stateful Word Count (2/4)

- ▶ The first micro batch contains a message `a`.
- ▶ `updateFunc = (key: String, value: Option[Int], state: State[Int]) => (key, sum)`
- ▶ Input: `key = a, value = Some(1), state = 0`

Example - Stateful Word Count (2/4)

- ▶ The **first micro batch** contains a message **a**.
- ▶ `updateFunc = (key: String, value: Option[Int], state: State[Int]) => (key, sum)`
- ▶ Input: `key = a, value = Some(1), state = 0`
- ▶ Output: `key = a, sum = 1`

Example - Stateful Word Count (3/4)

- ▶ The **second micro batch** contains messages **a** and **b**.

Example - Stateful Word Count (3/4)

- ▶ The **second micro batch** contains messages **a** and **b**.
- ▶ `updateFunc = (key: String, value: Option[Int], state: State[Int]) => (key, sum)`
- ▶ Input: `key = a, value = Some(1), state = 1`
- ▶ Input: `key = b, value = Some(1), state = 0`

Example - Stateful Word Count (3/4)

- ▶ The **second micro batch** contains messages **a** and **b**.
- ▶ `updateFunc = (key: String, value: Option[Int], state: State[Int]) => (key, sum)`
- ▶ Input: `key = a, value = Some(1), state = 1`
- ▶ Input: `key = b, value = Some(1), state = 0`
- ▶ Output: `key = a, sum = 2`
- ▶ Output: `key = b, sum = 1`

Example - Stateful Word Count (4/4)

- ▶ The **third micro batch** contains a message **b**.

Example - Stateful Word Count (4/4)

- ▶ The **third micro batch** contains a message **b**.
- ▶ `updateFunc = (key: String, value: Option[Int], state: State[Int]) => (key, sum)`
- ▶ Input: `key = b, value = Some(1), state = 1`

Example - Stateful Word Count (4/4)

- ▶ The **third micro batch** contains a message **b**.
- ▶ `updateFunc = (key: String, value: Option[Int], state: State[Int]) => (key, sum)`
- ▶ Input: `key = b, value = Some(1), state = 1`
- ▶ Output: `key = b, sum = 2`

Structured Streaming

Structured Streaming

- ▶ Treating a **live data stream** as a **table** that is being **continuously appended**.

Data stream as an unbounded table

Programming Model (1/2)

- ▶ Defines a **query** on the input table, as a **static table**.
 - Spark automatically converts this **batch-like query** to a **streaming execution plan**.

Programming Model (1/2)

- ▶ Defines a **query** on the input table, as a **static table**.
 - Spark automatically converts this **batch-like query** to a **streaming execution plan**.
- ▶ Specify **triggers** to control **when to update the results**.
 - Each time a trigger fires, Spark **checks for new data** (**new row** in the input table), and **incrementally** updates the result.

Programming Model (2/2)

User's batch-like query on input table

Incremental execution on streaming data

Output Modes

▶ **Three** output modes:

1. **Append**: only the new rows **appended to the result table** since the last trigger will be written to the external storage.

Output Modes

▶ **Three** output modes:

1. **Append**: only the new rows **appended to the result table** since the last trigger will be written to the external storage.
2. **Complete**: the **entire updated result table** will be written to external storage.

Output Modes

▶ **Three** output modes:

1. **Append**: only the new rows **appended to the result table** since the last trigger will be written to the external storage.
2. **Complete**: the **entire updated result table** will be written to external storage.
3. **Update**: only the rows that were **updated in the result table** since the last trigger will be changed in the external storage.

Five Steps to Define a Streaming Query (1/5)

- ▶ Define **input sources**.
- ▶ Use `spark.readStream` to create a `DataStreamReader`.

```
val spark = SparkSession.builder.master("local[2]").appName("appname").getOrCreate()

val lines = spark.readStream.format("socket")
    .option("host", "localhost")
    .option("port", 9999)
    .load()
```

Five Steps to Define a Streaming Query (2/5)

- ▶ Transform data.
- ▶ E.g., below `counts` is a `streaming DataFrame` that represents the running word counts.

```
import org.apache.spark.sql.functions._  
  
val words = lines.select(split(col("value"), "\\s").as("word"))  
  
val counts = words.groupBy("word").count()
```

Five Steps to Define a Streaming Query (3/5)

- ▶ Define **output sink** and **output mode**.
- ▶ Use `DataFrame.writeStream` to define how to write the processed output data.

```
val writer = counts.writeStream.format("console").outputMode("complete")
```

Five Steps to Define a Streaming Query (4/5)

- ▶ Specify processing details.

```
\\ word count details
import org.apache.spark.sql.streaming._

val checkpointDir = "...

val writer2 = writer
  .trigger(Trigger.ProcessingTime("1 second"))
  .option("checkpointLocation", checkpointDir)
```

Five Steps to Define a Streaming Query (5/5)

- ▶ Start the query.
- ▶ `streamingQuery` represents an **active query** and can be used to **manage the query**.

```
val streamingQuery = writer2.start()
```

Basic Operations (1/2)

- ▶ Most of operations on `DataFrame/Dataset` are **supported** for streaming.

```
case class Call(action: String, time: Timestamp, id: Int)

val df: DataFrame = spark.readStream.json("s3://logs")
val ds: Dataset[Call] = df.as[Call]
```

Basic Operations (1/2)

- ▶ Most of operations on `DataFrame/Dataset` are **supported** for streaming.

```
case class Call(action: String, time: Timestamp, id: Int)

val df: DataFrame = spark.readStream.json("s3://logs")
val ds: Dataset[Call] = df.as[Call]
```

- ▶ Selection and projection

```
df.select("action").where("id > 10") // using untyped APIs
ds.filter(_.id > 10).map(_.action) // using typed APIs
```

Basic Operations (2/2)

► Aggregation

```
df.groupBy("action") // using untyped API  
ds.groupByKey(_.action) // using typed API
```

Basic Operations (2/2)

▶ Aggregation

```
df.groupBy("action") // using untyped API  
ds.groupByKey(_.action) // using typed API
```

▶ SQL commands

```
df.createOrReplaceTempView("dfView")  
spark.sql("select count(*) from dfView") // returns another streaming DF
```

Google Dataflow and Beam

MillWheel Dataflow

- ▶ **MillWheel** is a framework for building **low-latency** data-processing applications.

MillWheel Dataflow

- ▶ **MillWheel** is a framework for building **low-latency** data-processing applications.
- ▶ A **dataflow graph** of **transformations** (**computations**).

MillWheel Dataflow

- ▶ **MillWheel** is a framework for building **low-latency** data-processing applications.
- ▶ A **dataflow graph** of **transformations** (**computations**).
- ▶ **Stream**: **unbounded data** of (**key, value, timestamp**) records.
 - Timestamp: **event-time**

Key Extraction Function and Computations

- ▶ Stream of (key, value, timestamp) records.
- ▶ **Key extraction function**: specified by the stream consumer to **assign keys** to records.

Key Extraction Function and Computations

- ▶ Stream of (key, value, timestamp) records.
- ▶ **Key extraction function**: specified by the stream consumer to **assign keys** to records.
- ▶ **Computation** can only access state for the **specific key**.
- ▶ **Multiple** computations can extract **different keys** from the **same stream**.

Persistent State

- ▶ Keep the **states** of the computations
- ▶ Managed on **per-key** basis
- ▶ Stored in **Bigtable** or **Spanner**
- ▶ Common use: **aggregation**, **joins**, ...

What is Google Cloud Dataflow?

Google Cloud Dataflow (1/2)

- ▶ Google managed service for unified **batch** and **stream** data processing.

Google Cloud Dataflow (2/2)

- ▶ Open source **Cloud Dataflow SDK**
- ▶ Express your data processing **pipeline** using **FlumeJava**.

Google Cloud Dataflow (2/2)

- ▶ Open source **Cloud Dataflow SDK**
- ▶ Express your data processing **pipeline** using **FlumeJava**.
- ▶ If you run it in **batch** mode, it executed on the **MapReduce** framework.

Google Cloud Dataflow (2/2)

- ▶ Open source **Cloud Dataflow SDK**
- ▶ Express your data processing **pipeline** using **FlumeJava**.
- ▶ If you run it in **batch** mode, it executed on the **MapReduce** framework.
- ▶ If you run it in **streaming** mode, it is executed on the **MillWheel** framework.

Windowing and Triggering

- ▶ **Windowing** determines **where** in **event time** data are grouped together for processing.

Windowing and Triggering

- ▶ **Windowing** determines **where** in **event time** data are grouped together for processing.
- ▶ **Triggering** determines **when** in **processing time** the results of groupings are emitted as panes.

Example (1/3)

- ▶ Batch processing

Example (2/3)

- ▶ Trigger at **period** (time-based triggers)

Example (2/3)

- ▶ Trigger at **period** (time-based triggers)
- ▶ Trigger at **count** (data-driven triggers)

Example (3/3)

- ▶ Fixed window, trigger at **period** (**micro-batch**)

Example (3/3)

- ▶ Fixed window, trigger at **period** (**micro-batch**)
- ▶ Fixed window, trigger at **watermark** (**streaming**)

Where is Apache Beam?

From Google Cloud Dataflow to Apache Beam

- ▶ In 2016, [Google Cloud Dataflow](#) team announced its intention to donate the [programming model](#) and [SDKs](#) to the Apache Software Foundation.

From Google Cloud Dataflow to Apache Beam

- ▶ In 2016, [Google Cloud Dataflow](#) team announced its intention to donate the [programming model](#) and [SDKs](#) to the Apache Software Foundation.
- ▶ That resulted in the incubating project [Apache Beam](#).

Programming Components

- ▶ Pipelines
- ▶ PCollections
- ▶ Transforms
- ▶ I/O sources and sinks

Pipelines

- ▶ A **pipeline** represents a **data processing job**.
- ▶ **Directed graph** of operating on data.
- ▶ A pipeline consists of **two** parts:
 - **Data** (**PCollection**)
 - **Transforms** applied to that data

PCollections (1/2)

- ▶ A **parallel collection** of records
- ▶ **Immutable**
- ▶ Must specify **bounded** or **unbounded**

PCollections (2/2)

```
// Create a Java Collection, in this case a List of Strings.  
static final List<String> LINES = Arrays.asList("line 1", "line 2", "line 3");  
  
PipelineOptions options = PipelineOptionsFactory.create();  
Pipeline p = Pipeline.create(options);  
  
// Create the PCollection  
p.apply(Create.of(LINES)).setCoder(StringUtf8Coder.of())
```

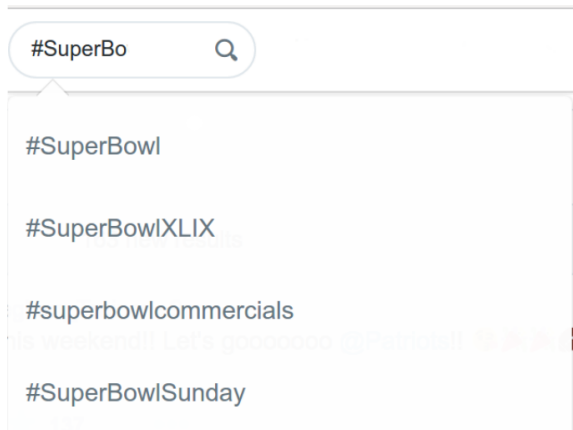

Transformations

- ▶ A **processing operation** that transforms data
- ▶ Each transform accepts **one (or multiple) PCollections** as input, performs an operation, and produces **one (or multiple)** new **PCollections** as output.
- ▶ Core transforms: **ParDo, GroupByKey, Combine, Flatten**

Example: HashTag Autocompletion (1/3)

Example: HashTag Autocompletion (2/3)

Example: HashTag Autocompletion (3/3)

```
Pipeline p = Pipeline.create();  
p.begin();
```

```
.apply(TextIO.Read.from("gs://..."))
```

```
.apply(ParDo.of(new ExtractTags()))
```

```
.apply(Count.perElement())
```

```
.apply(ParDo.of(new ExpandPrefixes()))
```

```
.apply(Top.largestPerKey(3))
```

```
.apply(TextIO.Write.to("gs://..."));
```

```
p.run();
```

Summary

Summary

- ▶ Spark
 - Mini-batch processing
 - DStream: sequence of RDDs
 - RDD and window operations
 - Structured streaming

- ▶ Google cloud dataflow
 - Pipeline
 - PCollection
 - Transforms
