The Questions-Answers Page

<https://tinyurl.com/hk7hzpw5>

Where Are We?

What do we do when there is **too much data** to process?

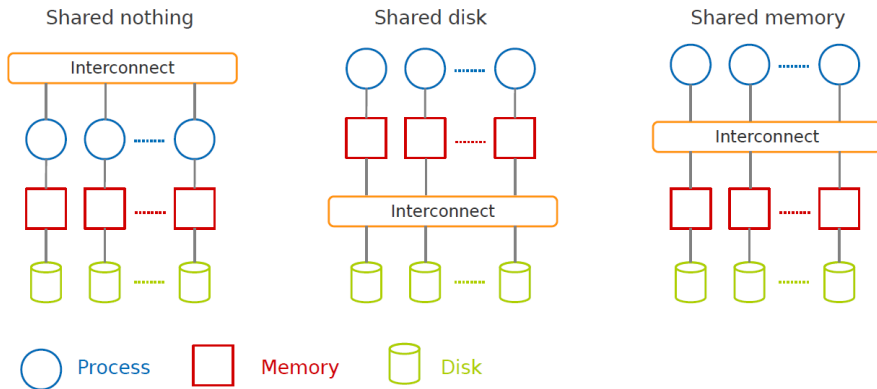

Scale Up vs. Scale Out

- ▶ Scale **up** or scale **vertically**: adding **resources** to a **single** node in a system.
- ▶ Scale **out** or scale **horizontally**: adding **more nodes** to a system.

Taxonomy of Parallel Architectures

DeWitt, D. and Gray, J. "Parallel database systems: the future of high performance database systems". ACM Communications, 35(6), 85-98, 1992.

MapReduce

- ▶ A **shared nothing** architecture for processing **large data** sets with a **parallel/distributed** algorithm on **clusters of commodity hardware**.

Challenges

- ▶ How to **distribute computation**?
- ▶ How can we make it **easy** to write **distributed programs**?
- ▶ Machines **failure**.

Simplicity

- ▶ **MapReduce** takes care of **parallelization**, **fault tolerance**, and **data distribution**.
- ▶ **Hide** system-level details from programmers.

[<http://www.johnlund.com/page/8358/elephant-on-a-scooter.asp>]

MapReduce Definition

- ▶ A **programming model**: to **batch** process large data sets (inspired by **functional programming**).
- ▶ An **execution framework**: to run parallel algorithms on **clusters of commodity hardware**.

Programming Model

**I'm glad I don't
have to hunt for
my food,**

**I don't even
know where
sandwiches live.**

Word Count

- ▶ Count the number of times each **distinct word** appears in the file
- ▶ If the file **fits in memory**: `words(doc.txt) | sort | uniq -c`

Word Count

- ▶ Count the number of times each **distinct word** appears in the file
- ▶ If the file **fits in memory**: `words(doc.txt) | sort | uniq -c`

- ▶ If not?

Data-Parallel Processing (1/2)

- ▶ Parallelize the data and process.

Data-Parallel Processing (2/2)

► MapReduce

MapReduce Stages - Map

- ▶ Each **Map task** (typically) operates on a **single HDFS block**.
- ▶ **Map tasks** (usually) run on the **node** where the **block** is stored.
- ▶ Each **Map task** generates a set of **intermediate key/value pairs**.

MapReduce Stages - Shuffle and Sort

- ▶ Sorts and consolidates **intermediate data** from all mappers.
- ▶ Happens **after** all **Map tasks** are complete and **before** **Reduce tasks** start.

MapReduce Stages - Reduce

- ▶ Each **Reduce** task operates on all **intermediate values** associated with the **same intermediate key**.
- ▶ Produces the **final output**.

MapReduce Data Flow (1/5)

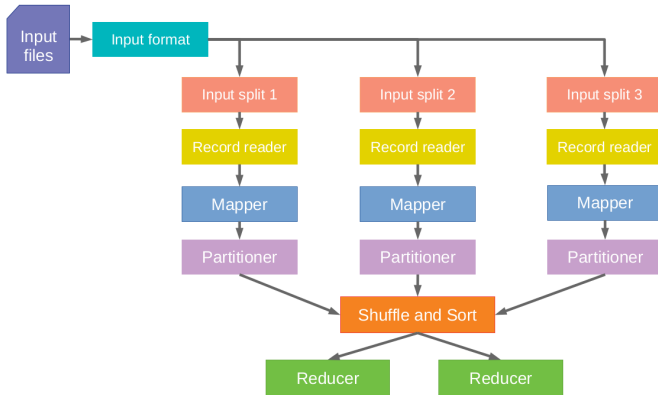

MapReduce Data Flow (2/5)

MapReduce Data Flow (3/5)

MapReduce Data Flow (4/5)

MapReduce Data Flow (5/5)

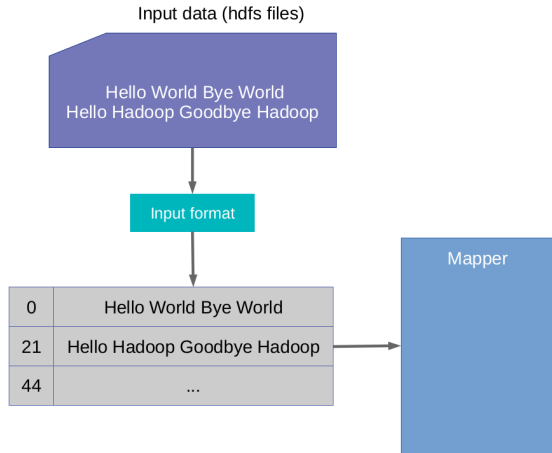

Word Count in MapReduce

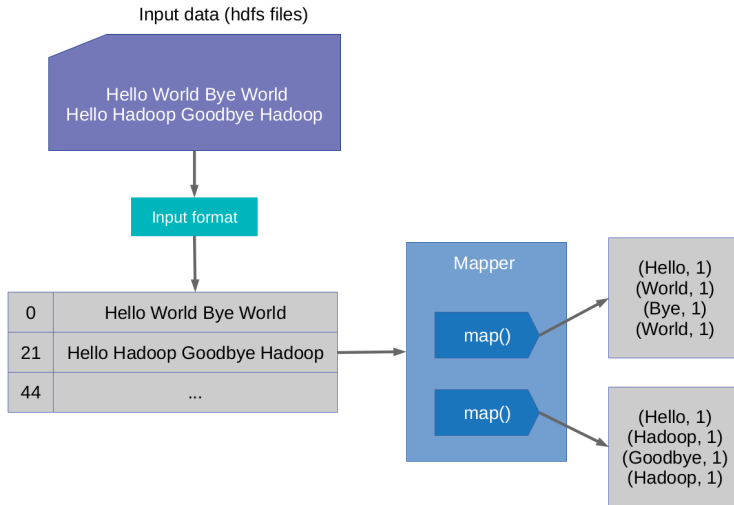

- ▶ Consider doing a **word count** of the following file using **MapReduce**

Word Count in MapReduce - Map (1/2)

Word Count in MapReduce - Map (2/2)

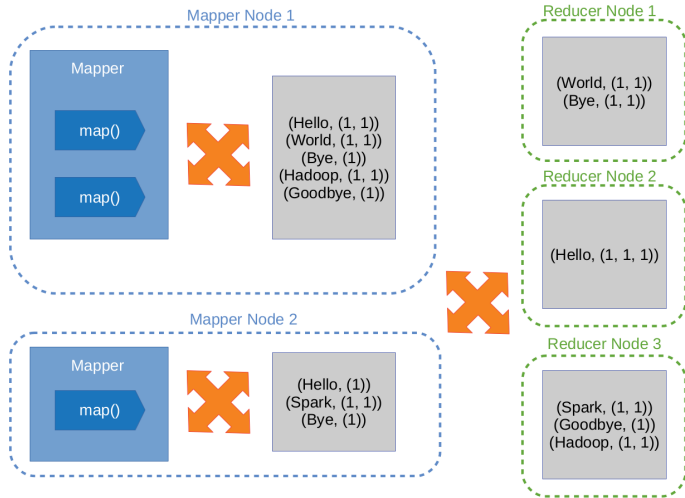

Word Count in MapReduce - Shuffle and Sort (1/3)

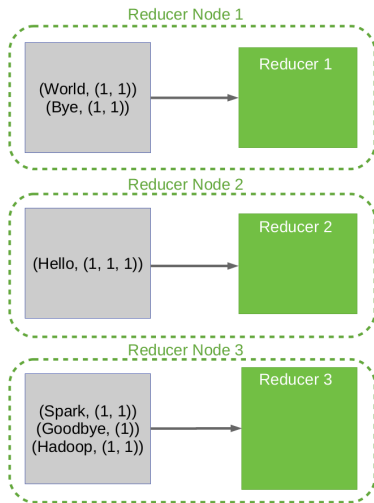

Word Count in MapReduce - Shuffle and Sort (2/3)

Word Count in MapReduce - Shuffle and Sort (3/3)

Word Count in MapReduce - Reduce (1/2)

Word Count in MapReduce - Reduce (2/2)

Mapper

The Mapper

- ▶ **Input:** (key, value) pairs
- ▶ **Output:** a list of (key, value) pairs

```
map(in_key, in_value) -> list of (inter_key, inter_value)
```

```
(in_key, in_value) ⇒ map() ⇒ (inter_key1, inter_value1)  
                               (inter_key2, inter_value2)  
                               (inter_key3, inter_value3)  
                               (inter_key4, inter_value4)
```

...

The Mapper

- ▶ **Input:** (key, value) pairs
- ▶ **Output:** a list of (key, value) pairs
- ▶ The Mapper may use or completely ignore the input key.

```
map(in_key, in_value) -> list of (inter_key, inter_value)
```

```
(in_key, in_value) ⇒ map() ⇒ (inter_key1, inter_value1)  
                                (inter_key2, inter_value2)  
                                (inter_key3, inter_value3)  
                                (inter_key4, inter_value4)
```

...

The Mapper

- ▶ **Input:** (key, value) pairs
- ▶ **Output:** a list of (key, value) pairs
- ▶ The Mapper may use or completely ignore the input key.
- ▶ A standard pattern is to read one line of a file at a time.
 - **Key:** the byte offset
 - **Value:** the content of the line

```
map(in_key, in_value) -> list of (inter_key, inter_value)
```

```
(in_key, in_value) ⇒ map() ⇒ (inter_key1, inter_value1)  
                               (inter_key2, inter_value2)  
                               (inter_key3, inter_value3)  
                               (inter_key4, inter_value4)
```

...

The Mapper Example (1/3)

- ▶ Turn input into `upper case`

```
map(k, v) = emit (k.to_upper, v.to_upper)
```

```
(kth, this is the course id2221) ⇒ map() ⇒ (KTH, THIS IS THE COURSE ID2221)
```

The Mapper Example (2/3)

- ▶ Count the **number of characters** in the input

```
map(k, v) = emit (k, v.length)
```

(kth, this is the course id2221) \Rightarrow `map()` \Rightarrow (kth, 26)

The Mapper Example (3/3)

- ▶ Turn each word in the input into pair of (word, 1)

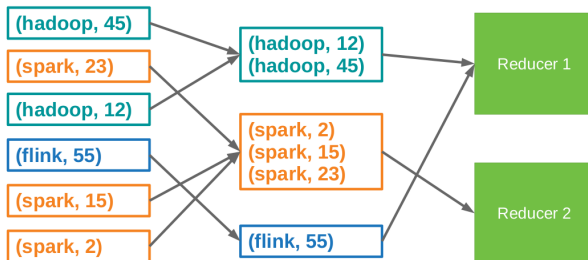

```
map(k, v) = foreach w in v emit (w, 1)
```

```
(21, Hello Hadoop Goodbye Hadoop) ⇒ map() ⇒ (Hello, 1)  
                                           (Hadoop, 1)  
                                           (Goodbye, 1)  
                                           (Hadoop, 1)
```

Reducer

Shuffle and Sort

- ▶ After the Map phase, all intermediate (key, value) pairs are grouped by the intermediate keys.
- ▶ Each (key, list of values) is passed to a Reducer.

The Reducer

- ▶ **Input:** (key, list of values) pairs
- ▶ **Output:** a (key, value) pair or list of (key, value) pairs
- ▶ The Reducer outputs zero or more final (key, value) pairs

```
reduce(inter_key, [inter_value1, inter_value2, ...]) -> (out_key, out_value)
```

```
(inter_k, [inter_v1, inter_v2, ...]) ⇒ reduce() ⇒ (out_k, out_v)
```

or

```
(inter_k, [inter_v1, inter_v2, ...]) ⇒ reduce() ⇒ (out_k, out_v1)  
                                                    (out_k, out_v2)  
                                                    ...
```

The Reducer Example (1/3)

- ▶ **Add up** all the values associated with each intermediate key

```
reduce(k, vals) = {  
  sum = 0  
  foreach v in vals sum += v  
  emit (k, sum)  
}
```

(Hello, [1, 1, 1]) ⇒ **reduce()** ⇒ (Hello, 3)

(Bye, [1]) ⇒ **reduce()** ⇒ (Bye, 1)

The Reducer Example (2/3)

- ▶ Get the **maximum** value of each intermediate key

```
reduce(k, vals) = emit (k, max(vals))
```

(KTH, [5, 1, 12, 7]) \Rightarrow **reduce()** \Rightarrow (KTH, 12)

The Reducer Example (3/3)

► Identify reducer

```
reduce(k, vals) = foreach v in vals emit (k, v)
```

```
(KTH, [5, 1, 12, 7]) ⇒ reduce() ⇒ (KTH, 5)  
                        (KTH, 1)  
                        (KTH, 12)  
                        (KTH, 7)
```

Example: Word Count - map

```
public static class MyMap extends Mapper<...> {
    private final static IntWritable one = new IntWritable(1);
    private Text word = new Text();

    public void map(LongWritable key, Text value, Context context)
        throws IOException, InterruptedException {
        String line = value.toString();
        StringTokenizer tokenizer = new StringTokenizer(line);

        while (tokenizer.hasMoreTokens()) {
            word.set(tokenizer.nextToken());
            context.write(word, one);
        }
    }
}
```

Example: Word Count - reduce

```
public static class MyReduce extends Reducer<...> {  
    public void reduce(Text key, Iterator<...> values, Context context)  
        throws IOException, InterruptedException {  
        int sum = 0;  
  
        while (values.hasNext())  
            sum += values.next().get();  
  
        context.write(key, new IntWritable(sum));  
    }  
}
```

Example: Word Count - driver

```
public static void main(String[] args) throws Exception {
    Configuration conf = new Configuration();
    Job job = new Job(conf, "wordcount");

    job.setOutputKeyClass(Text.class);
    job.setOutputValueClass(IntWritable.class);

    job.setMapperClass(MyMap.class);
    job.setCombinerClass(MyReduce.class);
    job.setReducerClass(MyReduce.class);

    job.setInputFormatClass(TextInputFormat.class);
    job.setOutputFormatClass(TextOutputFormat.class);

    FileInputFormat.addInputPath(job, new Path(args[0]));
    FileOutputFormat.setOutputPath(job, new Path(args[1]));

    job.waitForCompletion(true);
}
```

MapReduce Algorithm Design

MapReduce Algorithm Design

- ▶ Local aggregation
- ▶ Joining
- ▶ Sorting

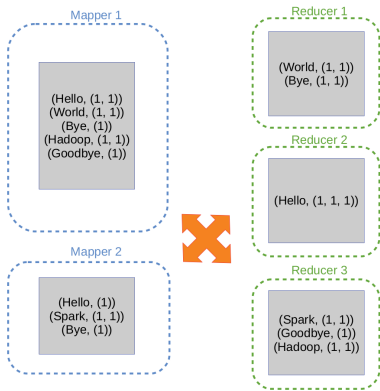

MapReduce Algorithm Design

- ▶ Local aggregation
- ▶ Joining
- ▶ Sorting

Local Aggregation - In-Map Combiner (1/2)

- ▶ In some cases, there is significant **repetition** in the **intermediate keys** produced by each **map** task, and the **reduce** function is **commutative** and **associative**.

Local Aggregation - In-Map Combiner (2/2)

- ▶ Merge partially data before it is sent over the network to the reducer.
- ▶ Typically the same code for the combiner and the reduce function.

MapReduce Algorithm Design

- ▶ Local aggregation
- ▶ Joining
- ▶ Sorting

Joins

- ▶ Joins are **relational** constructs you use to **combine relations together**.
- ▶ In MapReduce joins are applicable in situations where you have **two or more datasets you want to combine**.

Joins - Two Strategies

- ▶ **Reduce-side** join
 - **Repartition** join
 - When joining **two or more large** datasets together

- ▶ **Map-side** join
 - **Replication** join
 - When **one of the datasets is small** enough to cache

Joins - Reduce-Side Join

[M. Donald et al., MapReduce design patterns, O'Reilly, 2012.]

Joins - Map-Side Join

[M. Donald et al., MapReduce design patterns, O'Reilly, 2012.]

MapReduce Algorithm Design

- ▶ Local aggregation
- ▶ Joining
- ▶ **Sorting**

Sort (1/3)

- ▶ Assume you want to have your job output in **total sort order**.
- ▶ **Trivial** with a **single Reducer**.
 - **Keys** are passed to the Reducer in **sorted order**.

Sort (2/3)

- ▶ What if we have **multiple Reducer**?

Sort (3/3)

- ▶ For multiple Reducers we need to choose a **partitioning function**

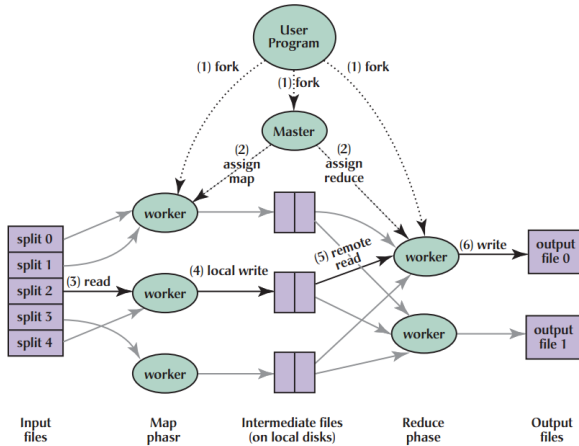

$$\text{key1} < \text{key2} \Rightarrow \text{partition}(\text{key1}) \leq \text{partition}(\text{key2})$$

Implementation

Architecture

MapReduce Execution (1/7)

- ▶ The **user program** divides the input files into **M splits**.
 - A typical size of a split is the size of a **HDFS** block (64 MB).
 - Converts them to **key/value** pairs.
- ▶ It starts up many copies of the program on a cluster of machines.

MapReduce Execution (2/7)

- ▶ One of the copies of the program is **master**, and the rest are **workers**.
- ▶ The **master** assigns works to the **workers**.
 - It picks **idle** workers and assigns each one a **map** task or a **reduce** task.

MapReduce Execution (3/7)

- ▶ A **map worker** reads the contents of the corresponding input **splits**.
- ▶ It parses key/value pairs out of the input data and passes each pair to the **user defined map function**.
- ▶ The **key/value** pairs produced by the **map** function are buffered in **memory**.

MapReduce Execution (4/7)

- ▶ The buffered pairs are **periodically** written to **local disk**.
 - They are partitioned into **R regions** ($\text{hash}(\text{key}) \bmod R$).
- ▶ The **locations** of the buffered pairs on the local disk are passed back to the **master**.
- ▶ The **master** forwards these locations to the **reduce workers**.

MapReduce Execution (5/7)

- ▶ A **reduce worker reads** the buffered data from the local disks of the map workers.
- ▶ When a reduce worker has read all intermediate data, it sorts it by the **intermediate keys**.

MapReduce Execution (6/7)

- ▶ The reduce worker iterates over the **intermediate data**.
- ▶ For each **unique intermediate key**, it passes the key and the corresponding set of intermediate values to the **user defined reduce function**.
- ▶ The output of the reduce function is appended to a **final output file** for this reduce partition.

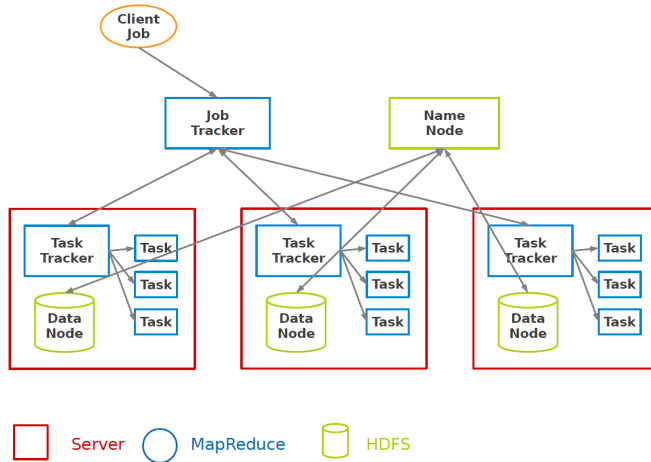

MapReduce Execution (7/7)

- ▶ When all map tasks and reduce tasks have been completed, the **master** wakes up the **user program**.

Hadoop MapReduce and HDFS

Fault Tolerance - Worker

- ▶ Detect failure via **periodic heartbeats**.
- ▶ Re-execute **in-progress map** and **reduce** tasks.
- ▶ Re-execute **completed map** tasks: their output is stored on the local disk of the failed machine and is therefore inaccessible.
- ▶ **Completed reduce** tasks do not need to be re-executed since their output is stored in a global filesystem.

Fault Tolerance - Master

- ▶ State is periodically **checkpointed**: a new copy of master starts from the last checkpoint state.

Summary

Summary

- ▶ Scaling out: shared nothing architecture
- ▶ MapReduce
 - Programming model: Map and Reduce
 - Execution framework
